Topic

Auxiliary Terms and Local Gates

Submission

Submit one ZIP archive containing report.pdf, the configuration file, and the minimal code needed to reproduce the run. The maximum file size is 25 MB.

Problems

1. Specify the input, output, and stopping condition for a minimal implementation of Auxiliary Terms and Local Gates.

$$r_a \rightarrow cluster(x_a, E_a, \rho_a, I_a)$$

2. Implement one accepted and one rejected update. Preserve the data version, configuration, seed, and decision record.

$$\Delta T_a = G_c(x_a) f_a(\eta_c)$$

3. Run a negative control, report the observed failure mode, and explain whether the acceptance rule behaved as intended.

$$|\partial \Delta T_a / \partial \eta_c| < \epsilon_{outsidec}$$

Show enough intermediate work that another student can reproduce the calculation.
